Before this lab, I thought looking at a dataset meant reading through the table. The Iris data showed me that isn't enough, the numbers told me almost nothing, but the scatter plot showed right away that setosa is separate while versicolor and virginica overlap. That changed how I think about the first step with any dataset. Now I want to plot it before I do anything else. It also showed me that if two classes overlap on two features, a model may struggle to separate them, which is why I want to test whether the petal measurements do better. Writing the observations was harder than the code, because explaining why the species make me think about what the data means, not just what it looks like. I also learned that the load, inspect, and plot workflow is the same for numeric data as for the text data in my NLP class, so these skills will carry over to my other work.

Starting my first semester studying Artificial Intelligence as a complete beginner, I initially felt nervous about using cloud-based platforms and navigating interactive notebooks. Working through this assignment step-by-step helped build my confidence, especially when I felt confused about how to export my completed file directly from the browser. Seeking extra guidance and following clear troubleshooting steps taught me that encountering small obstacles is a normal part of learning. Following structured steps, asking for help when stuck, and verifying my outputs will be essential habits as I continue through my AI studies.
